Chapter 1. Atom (electrons; atomic orbitals)

Chapter 2. Chemical Bondings (ionic vs covalent bonding)

Chapter 3. Molecular Structures and Shapes

Lecture 3. Structure and Shape of Molecules

1) VSEPR (Valence Shell Electron Pair Repulsion) model
2) VB (Valance Bond) theory
3) MO (Molecular Orbital) theory

1) Valance Shell Electron Pair Repulsion (VSEPR)

Lewis structure shows the linkages and lone pairs 2-dimensionally.

VSEPR model suggests the **3D arrangement** of atoms and shape of molecules

1. Only the positions of atoms are considered to identify the molecular shape.

2. Treat multiple bond as a single region with high electron density.

3. Minimize repulsions between lone pair (LP) – LP (1), bonding pair (BP) – LP (2), or BP – BP (3). Arrange them as far as possible.
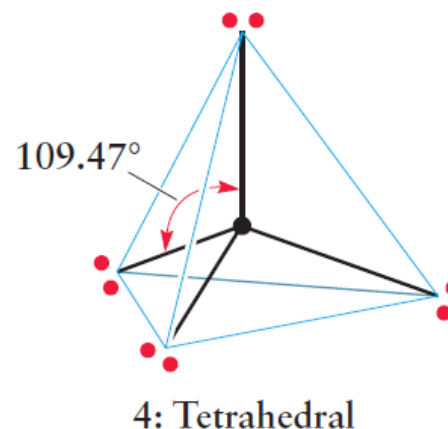

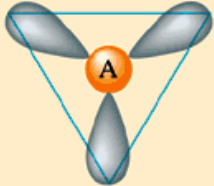

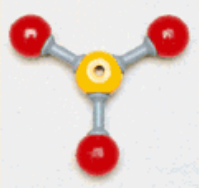

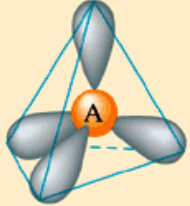

Valence Shell Electron Pair Repulsion:
The structure around a given atom is determined *principally* by minimizing electron pair repulsions.
3.1. VSEPR Model

Steric Number of the central atom

SN = # of atoms bonded to c.a.
    + # of lone pairs on c.a.

AX_3E		NH_3			
AX_3E_2		ClF_3			

Correction)
BrF$_3$ is not a AX$_3$, but is AX$_3$E$_2$-type molecule.
BF$_3$ is a AX$_3$-type one.

Valence Bond Theory

- An approximate <u>Quantum Theory</u> that solves problem of Lewis/VSEPR.

- A bond is formed by the two electrons placed in the overlapped region of <u>atomic orbitals</u> of two atoms.
Valance Bond Theory explains covalent bonding with atomic orbitals

$y^3 - 3yx^2$ $5yz^2 - yr^2$ $x^3 - 3xy^2$

3.4. Orbital Overlap: Bonding!
σ bond:

- No nodal plane <u>including bond axis</u>

- Cylindrical or sausage shape
π bond

- Nodal plane <u>including bonding axis</u>

- lobes
Examples
33 Hydrogen fluoride, HF
Multiple bond = one **σ** bond + the other **π** bonds

Comparison of VB and Lewis/VSEPR

- In Lewis/VSEPR theory, shapes of molecules are determined by bond-bond repulsion

- In VB, shapes are determined by the orientation of **overlapped orbitals.**

3.5. Hybridization of Orbitals
1   Methane, CH_4

all the C-H bonds
are equivalent.

Electron promotion and Hybrid orbital

35   Carbon, $[He]2s^2 2p_x^1 2p_y^1$

36   Carbon, $[He]2s^1 2p_x^1 2p_y^1 2p_z^1$

38   sp³ hybridized carbon
Electron promotion: electron relocation to a higher-energy orbital

Hybrid orbital: hybridizing orbitals

General Rules for Hybridization

- Number of hybrid orbitals
  = number of atomic orbitals used (one s + three p orbitals = four sp^3 orbitals).

- To form covalent bonds, hybrid orbitals may overlap either with atomic or hybrid orbitals.

- Molecular shape is determined by the shapes and orientations of hybrid orbitals, which are different from the shapes and orientations of atomic orbitals.

- Therefore, CH_4 is in <u>tetrahedral shape</u> even though the atomic orbitals of the carbon atom are <u>perpendicular</u> each other (90°).

Bonding in NH$_3$
N: 1s^2 **2s^2**
   2p^3

4sp^3

1) sp³ hybridization

4 sp³ hybrids

$$h_1 = \frac{1}{2}(s + px + py + p_z)$$

$$h_2 = \frac{1}{2}(s + px - p_y - p_z)$$

$$h_3 = \frac{1}{2}(s - p_x + p_y - p_z)$$

$$h_4 = \frac{1}{2}(s - p_x - p_y + p_z)$$

$$t_1 = (1/2)(s + p_x + p_y + p_z)$$

$$t_2 = (1/2)(s + p_x - p_y - p_z)$$

$$t_3 = (1/2)(s - p_x + p_y - p_z)$$

$$t_4 = (1/2)(s - p_x - p_y + p_z)$$
2) sp² & sp hybridization

3 sp² hybrids

$$h_1 = s + 2^{1/2} p_y$$

$$h_2 = s + (3/2)^{1/2}p_x - (1/2)^{1/2}p_y$$

$$h_3 = s - (3/2)^{1/2}p_x - (1/2)^{1/2}p_y$$
2 sp hybrids

$$h_1 = s + p_z$$

$$h_2 = s - p_z$$

(a) The σ-bond framework
(b) Formation of π-bonds by the overlap of half-filled 2p orbitals

σ: C(sp)—C(sp)   π: C(2p)—C(2p)

σ: C(sp)—H(1s)

σ: H(1s)—C(sp)

π: C(2p)—C(2p)
(c) Hybridization and bonding scheme

In Lewis structure,
double bond == two identical single bonds

In VB theory,
double bond = sigma bond + pi bond
Triple bond = sigma bond + two pi bonds

3) sp³d & sp³d² hybridization
Hybridization Schemes

Electron arrangement around the central atom	Hybrid orbitals (number)	Angle(s) between σ-bonds	Example(s) [underlined atom]

F
Q) Hybrid orbital only for sigma bonding?
: The shape/directionality of the hybrid orbitals allows only sigma bonding.

(b)

(a) The σ-bond framework
Q) What is the orbital of the Nitrogen in N_2?
: Again, use the hybrid orbital only when it is necessary.
In fact, we rarely use the hybrid orbital for the terminal atoms and diatomic molecules.

Egg and Chicken probem:
How do we know which hybrid scheme to use?

- Hybridization in itself CANNOT predict molecular shape. It can only explain which atomic orbital contributes to the bond.

Example)

   Known tetrahedral shape of methane

→ sp^3 hybrid → bonding of sp^3 and H atoms
